3. Volcano plot

The purpose of this analysis is to identify stalagmite enriched taxa in comparison to the extraction blank. I'm focussing on the subset of contigs annotated at genus level. q-values shown on the y-axis are obtained from a permutation test.

3.1 Genus abundance table

```
genus_wide= data %>% group_by(sample, genus) %>% summarize(summed_TPM=sum(tpm))%>% mutate(across(where(
## `summarise()` has grouped output by 'sample'. You can override using the
## `.groups` argument.
rownames(genus_wide)=genus_wide[,1]
genus_wide=genus_wide[,-1]
```

3.2 Calculate prevalence of genera

```
compute_prevalence = function(abund_df, control_prefix = "EXB", sample_prefix = "TDM", epsilon = 1e-6) {  
  # Identify which rows are controls and which are samples  
  control_rows = grepl(paste0("^", control_prefix), rownames(abund_df))  
  sample_rows = grepl(paste0("^", sample_prefix), rownames(abund_df))  
  # Compute prevalence (fraction of samples with non-zero abundance)  
  prev_control = colSums(abund_df[control_rows, , drop = FALSE] > 0, na.rm = TRUE)  
  prev_sample = colSums(abund_df[sample_rows, , drop = FALSE] > 0, na.rm = TRUE)  
  # Combine results into data frame  
  prevalence_df = data.frame(  
    Taxon = names(prev_sample),

    stringsAsFactors = FALSE  
  )  
  return(prevalence_df)  
}  
  
genus_prevalence_df = compute_prevalence(genus_wide)
```

3.3 CLR transformation

```
clr_transform = function(df, pseudocount = 1e-6) {  
  df = df + pseudocount  
  log_df = log(df)  
  gm_mean = rowMeans(log_df)

  return(clr_df)}
